## 2 Instructions

### 2.1 Running The Code

### 2.2 Generating the Figures

### 2.3 Modifying the Code

## 3 Algorithms

The algorithms presented

### 3.1 Preliminaries

We consider a Markov control process  $\mathcal{H}$ , which is defined in [?] as a 3-tuple:

$$\mathcal{H} = (\mathcal{X}, \mathcal{U}, Q) \tag{1}$$

where  $\mathcal{X} \subseteq \mathbb{R}^n$  is the state space,  $\mathcal{U} \subseteq \mathbb{R}^m$  is the control space, and  $Q$  is a stochastic kernel  $Q : \mathcal{B}(\mathcal{X}) \times \mathcal{X} \times \mathcal{U} \rightarrow [0, 1]$ , which is a Borel-measurable function that maps a probability measure  $Q(\cdot | x, u)$  to each  $x \in \mathcal{X}$  and  $u \in \mathcal{U}$  in the Borel space  $(\mathcal{X}, \mathcal{B}(\mathcal{X}))$ . A Markov control process can describe a wide class of stochastic, time-invariant systems, that can have either linear or nonlinear dynamics, as well as non-Gaussian disturbances. We consider a set  $\mathcal{S}$  of  $M$  samples of the form  $\{(\bar{x}_i, \bar{u}_i, \bar{y}_i)\}_{i=1}^M$  taken from the stochastic kernel, such that  $\bar{y}_i$  is drawn i.i.d. from the stochastic kernel  $Q$ , and  $\bar{u}_i$  is drawn from a fixed Markov policy  $\pi$ .

$$\bar{y}_i \sim Q(\cdot | \bar{x}_i, \bar{u}_i) \tag{2}$$

$$\bar{u}_i = \pi(\bar{x}_i) \tag{3}$$

The samples can be generated experimentally or via simulation, meaning they can be taken from real observations of the system evolution, or they can be generated using a known model. For demonstration purposes, all examples use samples collected via simulation. Once the samples are generated, the algorithm assumes no knowledge of the stochastic kernel  $Q$  or the disturbance.

### 3.2 Kernel Distribution Embeddings Backward Recursion Algorithm

### 3.3 Kernel Distribution Embeddings Backward Recursion (RFF) Algorithm

## 4 Problems

### 4.1 Terminal-Hitting Time Problem

### 4.2 First-Hitting Time Problem

## 5 Systems

The algorithms accept sample data drawn from a stochastic kernel  $Q$ . The data should be formatted such that the realizations of the stochastic kernel are formatted into the columns of a sample vector

$$\bar{x} = [\bar{x}_1, \dots, \bar{x}_M] \quad (4)$$

$$\bar{u} = [\bar{u}_1, \dots, \bar{u}_M] \quad (5)$$

$$\bar{y} = [\bar{y}_1, \dots, \bar{y}_M] \quad (6)$$

where the number of columns is  $M$ , and the number of rows is the dimensionality of the samples. For example, if  $\bar{x}_i, \bar{y}_i \in \mathbb{R}^n$ ,  $\bar{x}$  and  $\bar{y}$  should be  $[n \times M]$ .

### 5.1 System Samples

The system input to the algorithms is a set of samples organized in a class called `SystemSamples`. For example, to generate samples for the discrete-time double integrator system with sampling time  $T = 0.25$ ,

$$\mathbf{x}_{k+1} = \begin{bmatrix} 1 & T \\ 0 & 1 \end{bmatrix} \mathbf{x}_k + \begin{bmatrix} \frac{T^2}{2!} \\ T \end{bmatrix} u_k + \mathbf{w}_k \quad (7)$$

```
1  % Dimensionality of the state space samples.
2  n = 2;
3  % Dimensionality of the input space samples.
4  m = 2;
5  % Sampling time.
6  T = 0.25;
7
8  % Number of samples.
9  M = 1000;
10
11 % Compute random initial states sampled from a zero-mean Gaussian.
12 X = randn(n, M);
13 % Compute the input samples. For this example, the input is chosen to be 0.
14 U = zeros(m, M);
15 % Compute the disturbance.
16 W = randn(n, M);
17
18 % Construct the state and input matrices.
19 A = [1 T; 0 1];
20 B = [(T^2)/2!; T];
21
22 % compute the output samples.
23 Y = A*X + B*U + W;
```

```
24
25 % Create a SystemSamples object.
26 samples = SystemSamples('X', X, 'U', U, 'Y', Y);
```
